

Simplifying, Regularizing and Strengthening Sum-Product Network Structure Learning

Antonio Vergari, Nicola Di Mauro and Floriana Esposito

ECML-PKDD 2015 - 7 - 11 September Porto, Portugal

Introduction

The main task on *Probabilistic Graphical Models* (PGMs), *inference*, is untractable.

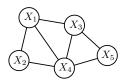

Tractable PGMs are recently gaining interest: tree based models [Meilă and Jordan 2000], Arithmetic Circuits (ACs) [Rooshenas and Lowd 2014], **Sum-Product Networks** (SPNs) [Poon and Domingos 2011].

Sum-Product Networks structure learning: LearnSPN.

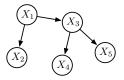

Improving LearnSPN on *structure quality* and *accuracy*, in three ways:

- I **simplifying** by limiting node splits
- II regularizing by effective early stopping
- III strengthening by model averaging

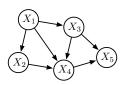

PGMs and Tractability

 $P(\mathbf{X}) = \frac{1}{Z} \prod_{c} \phi_c(\mathbf{X}_c)$

$$P(\mathbf{X}) = \prod_{i=1}^{n} P(X_i | Pa_i)$$

 $P(\mathbf{X}) = \prod_{i=1}^{n} P(X_i | \mathbf{Pa}_i)$

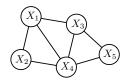

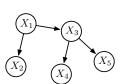

$$P(\mathbf{X}) = \prod_{i=1}^{n} P(X_i)$$

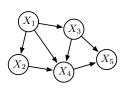

PGMs and Tractability

untractable

tractable

untractable

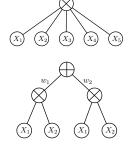

tractable

Sum-Product Networks (I)

SPNs are DAGs *compiling* the partition function of a joint pdf into a *deep* architecture of **sum** and **product** nodes.

Product nodes define factorizations over independent components, sum nodes weighted mixtures. Leaves are tractable univariate distributions.

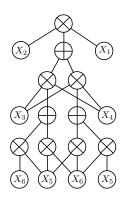

Products over nodes with different scopes (decomposability) and sums over nodes with same scopes (completeness) guarantee modeling a pdf (validity).

The **size** of the network is the number of *edges* in it.

The *depth* of the network is the number of alternated *layers*.

Sum-Product Networks (II)

Bottom-up evaluation of the network:

$$S_{X_i}(x_j) = P(X_i = x_j)$$

$$S_{+}(\mathbf{x}) = \sum_{i \in ch(+)} w_i S_i(\mathbf{x}), \quad S_{\times}(\mathbf{x}) = \prod_{i \in ch(\times)} S_i(\mathbf{x})$$

Inferences linear in the size of the network (# edges):

$$\oplus Z = S(*)$$

$$\oplus P(\mathbf{e}) = S(\mathbf{e})/S(*)$$

$$\oplus P(\mathbf{q}|\mathbf{e}) = \frac{P(\mathbf{q},\mathbf{e})}{P(\mathbf{e})} = \frac{S(\mathbf{q},\mathbf{e})}{S(\mathbf{e})}$$

 $\oplus MPE(\mathbf{q}, \mathbf{e}) = \max_{\mathbf{q}} P(\mathbf{q}, \mathbf{e}) = S^{max}(\mathbf{e})$ (by substituting sum nodes with *max* nodes)

How and Why Structure Learning

Fixed structures are hard to engineer and train (fully connected layers).

Automatic discovery of latent vars.

Constraint-based search formulation. Discover hidden variables for sum node mixtures and independences for product node components:

- greedy top-down: KMeans on features [Dennis and Ventura 2012]; alternating clustering on instances and independence tests on features, LearnSPN [Gens and Domingos 2013]
- greedy bottom up: merging feature regions by a Bayesian-Dirichlet independence test, and reducing edges by maximizing MI [Peharz, Geiger, and Pernkopf 2013]
- ID-SPN: turning LearnSPN in log-likelihood guided expansion of sub-networks approximated by Arithmetic Circuits [Rooshenas and Lowd 2014]

Why Structure Quality Matters

Tractable inference is guaranteed if the network size is polynomial in # vars.

Smaller networks, faster inference (comparing network sizes is better than comparing inference times).

Deeper networks are possibly more expressively efficient [Martens and Medabalimi 2014; Zhao, Melibari, and Poupart 2015].

Structural simplicity as a bias: overcomplex networks may not generalize well.

Structure quality desiderata: smaller but accurate, deeper but not wider, SPNs.

LearnSPN (I)

Build a tree-like SPN by recursively split the data matrix:

 \oplus splitting columns into pairs by a greedy *G Test* based procedure with threshold ρ :

$$G(X_i, X_j) = 2 \sum_{x_i \sim X_i} \sum_{x_j \sim X_j} c(x_i, x_j) \cdot \log \frac{c(x_i, x_j) \cdot |T|}{c(x_i)c(x_j)}$$

 \oplus clustering instances into |C| sets with **online Hard-EM** with cluster penalty λ :

$$Pr(\mathbf{X}) = \sum_{C_i \in \mathbf{C}} \prod_{X_j \in \mathbf{X}} Pr(X_j | C_i) Pr(C_i)$$

weights are estimated as cluster proportions

- \oplus if there are less than m instances, put a **naive factorization** over leaves
- \oplus each univariate distribution get **ML estimation** smoothed by lpha

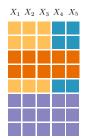

Hyperparameter space: $\{\rho, \lambda, m, \alpha\}$.

	X_1	X_2	X_3	X_4	X_5
!					
ŀ					
5					
6					
7					

X₁ X₂ X₃ X₄ X₅

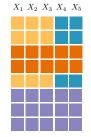

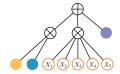

LearnSPN (II)

LearSPN performs two interleaved *greedy hierarchical* divisive *clustering* processes (co-clutering on the data matrix).

Fast and simple. But both processes never look back and are committed to the choices they take.

Online EM does not need to specify the number of clusters k in advance. But overcomplex structures are learned by exploding the number of sum node children.

Tractable leaf estimation. But naive factorization independence assumptions may be too strong.

ML estimations are effective. But they are not robust to noise, they can overfit the training set easily.

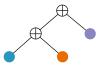

Simplifying by limiting node splits

Observation: each clustering process benefits from the other one improvements/highly suffers from other's mistakes.

Idea: slowing down the processes by limiting the number of nodes to split into. SPN-B, variant of LearnSPN that uses EM for mixture modeling with k=2 to cluster rows. No need for λ anymore.

Objectives:

- not committing to complex structures too early
- same expressive power as LearnSPN
- ⊕ reducing node out fan increases the depth
- ⊕ same accuracy, smaller networks

SPN-B: depth VS size

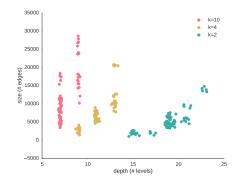

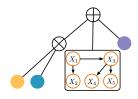

Figure : Comparing network sizes and depths while varying the max number of sum node children splits ($k \in \{10,4,2\}$). Each dot is an experiment in the grid search hyperparameter space performed by SPN-B on the dataset Plants.

Regularizing by effective early stopping

LearnSPN regularization is governed by α and m, however can be very ineffective:

- naive factorizations are too strong assumptions
- \oplus best likelihood structures prefer smaller values for m to get accurate naive factorizations

Idea: substituting naive factorizations with Bayesian trees as leaf distributions $P(\mathbf{X}) = \prod_i P(X_j | Pa_j)$:

- ⊕ learnable with Chow-Liu algorithm
- still tractable (linear) multivariate distributions for marginals, conditionals and MPE
- ⊕ same or higher accuracy
- \oplus less complex structures for larger values of m

SPN-BT: preserving likelihoods

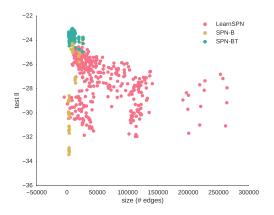

Figure: Comparing the network sizes against the average test log-likelihood obtained by LearnSPN, SPN-B and SPN-BT. Each dot is an experiment in the grid search performed for the dataset Pumsh-star.

SPN-BT: effective early stopping

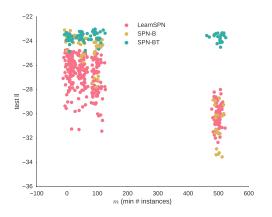

Figure: Comparing the values for m (10, 50, 100, 500) against the average test log-likelihood obtained by LearnSPN, SPN-B and SPN-BT. Each dot is an experiment in the grid search performed for the dataset Pumsb-star.

Strengthening by model averaging

Interpreting sum nodes as *general additive estimators*. Leveraging classic statistical tools to learn them: *bagging*.

Draw k bootstrapped samples from the data, then grow an SPN S_{B_i} on each of them. Join them into a single SPN \hat{S} with a sum node:

$$\hat{S} = \sum_{i=1}^{k} \frac{1}{k} S_{B_i}$$

More robustness and less variance in the model.

Exponential number of nodes if done for each sum node (bootstrapping only at the root).

Two variants in the experiments: SPN-BB and SPN-BTB, whether Chow-Liu trees are employed or not.

Bagging exp

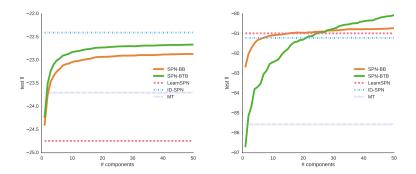

Table: Comparing test log-likelihoods for SPN-BB and SPN-BTB while increasing the number of components against LearnSPN, MT and ID-SPN best models accuracies for Pumsb_star (left) and DNA (right)

Experimental setting

Classical setting for *generative* PGMs structure learning *[Gens and Domingos 2013]*:

- 19 binary datasets from classification, recommendation, frequent pattern mining... [Lowd and Davis 2010] [Haaren and Davis 2012]
- ⊕ Training 75% Validation 10% Test 15% splits (no cv)

Observing both structure quality parameters and the network accuracy:

- ⊕ test set average log-likelihood
- ⊕ network *size* (# edges) and network *depth* (# levels)

We perform a model selection via a *grid search* in the same parameter space for LearnSPN, SPN-B, SPN-BT:

- $\oplus \ \lambda \in \{0.2, 0.4, 0.6, 0.8\}, \quad \oplus \ m \in \{1, 50, 100, 500\},\$
- $\oplus \ \rho \in \{5, 10, 15, 20\}, \qquad \quad \oplus \ \alpha \in \{0.1, 0.2, 0.5, 1.0, 2.0\}.$

Up to 50 components and best grid parameters for SPN-BB and SPN-BTB. Comparing II against LearnSPN, ID-SPN and MT [Meilă and Jordan 2000].

Network sizes

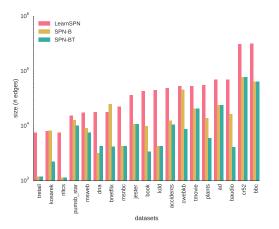

Figure: Comparing network sizes for the networks scoring the best log-likelihoods in the grid search as obtained by LearnSPN, SPN-B and SPN-BT for each dataset.

Network depths

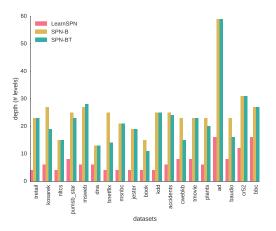

Figure: Comparing network depths for the networks scoring the best log-likelihoods in the grid search as obtained by LearnSPN, SPN-B and SPN-BT for each dataset.

Table: Average test log likelihoods for the best networks learned by all algorithms on all datasets after the grid search. In bold the values that are statistically better than all the others according to a Wilcoxon signed rank test with *p*-value of 0.05.

Conclusions

- Structure quality evaluation matters
- Deeper networks by applying a simplicity bias when splitting
- ⊕ Regularized SPNs by introducing Chow-Liu trees as leaves
- More robust and accurate SPNs with bootstrapped sum nodes

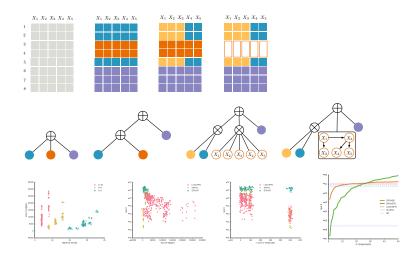

Further works

- ⊕ Are other sum node interpretations as gam effective?
- ⊕ Is it possible to compress learned structures?
- How these variations influence representation learning?
- ⊕ How can these variations be generalized to other tractable PGMs?
